## 1 Homework 6

### 1.1 References

- Lectures 21-23 (inclusive).

### 1.2 Instructions

- Type your name and email in the "Student details" section below.
- Develop the code and generate the figures you need to solve the problems using this notebook.
- For the answers that require a mathematical proof or derivation you should type them using latex. If you have never written latex before and you find it exceedingly difficult, we will likely accept handwritten solutions.
- The total homework points are 100. Please note that the problems are not weighed equally.

### 1.4 Problem 1 - Defining priors on function spaces

In this problem, we will explore further how Gaussian processes can be used to define probability measures over function spaces. To this end, assume that there is a 1D function, call if $f(x)$, which we do not know. For simplicity, assume that $x$ takes values in $[0, 1]$. We will employ Gaussian process regression to encode our state of knowledge about $f(x)$ and sample some possibilities. For each of the cases below: + Assume that $f \sim \text{GP}(m, k)$ and pick a mean ($m(x)$) and a covariance function $f(x)$ that match the provided information. + Write code that samples a few times (up to five) the values of $f(x)$ at 100 equidistant points between 0 and 1.

#### 1.4.1 Part A - Super smooth function with known length scale

Assume that you hold the following beliefs + You know that $f(x)$ has as many derivatives as you want and they are all continuous + You don't know if $f(x)$ has a specific trend. + You think that $f(x)$ has "wiggles" that are approximatly of size $\Delta x = 0.1$. + You think that $f(x)$ is between -4 and 4.

**Answer:**

**I am doing this for you so that you have a concrete example of what is requested.**

The mean function should be:

$$m(x) = 0.$$

The covariance function should be a squared exponential:

$$k(x, x') = s^2 \exp\left\{-\frac{(x - x')^2}{2\ell^2}\right\},$$

with variance:

$$s^2 = k(x, x) = \mathbb{V}[f(x)] = 4,$$

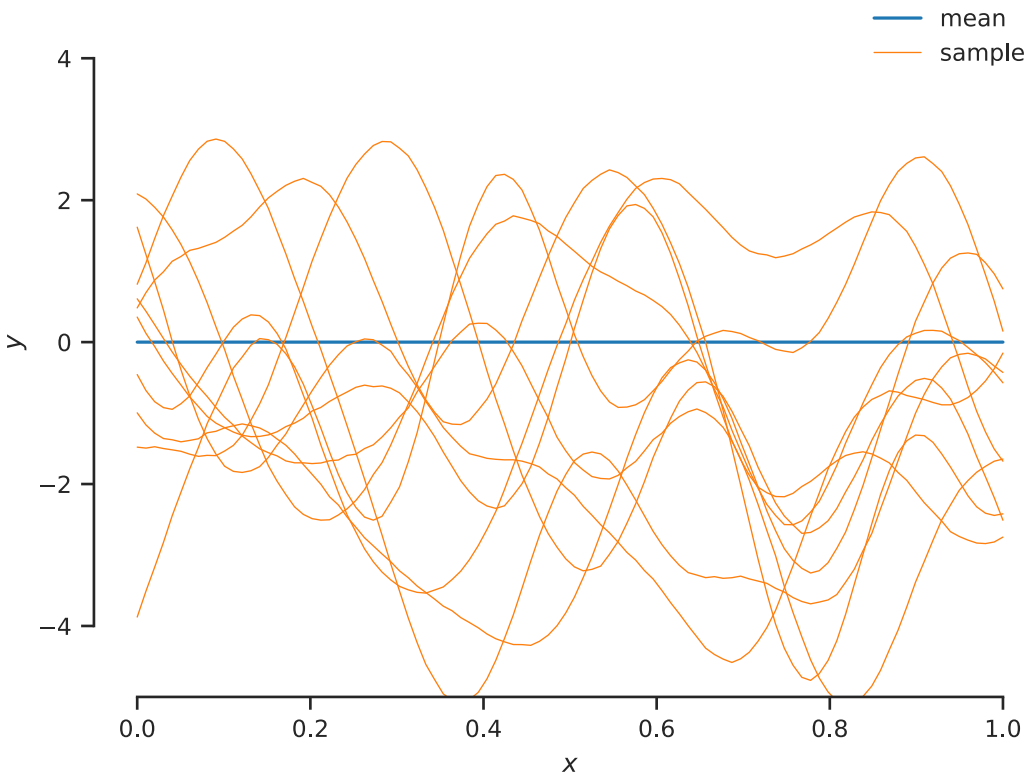
and lengthscale $\ell = 0.1$. We chose the variance to be 4.0 so that with (about) 95% probability, the values of $f(x)$ are between -4 and 4.

[ ]:
```
import torch
import gpytorch
from gpytorch.kernels import RBFKernel, ScaleKernel

# Define the covariance function
k = ScaleKernel(RBFKernel())
k.outputscale = 4.0
k.base_kernel.lengthscale = 0.1

# Define the mean function
mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

# Sample functions
sample_functions(mean, k, nugget=1e-4)
```



### 1.4.2 Part B - Super smooth function with known ultra-small length scale

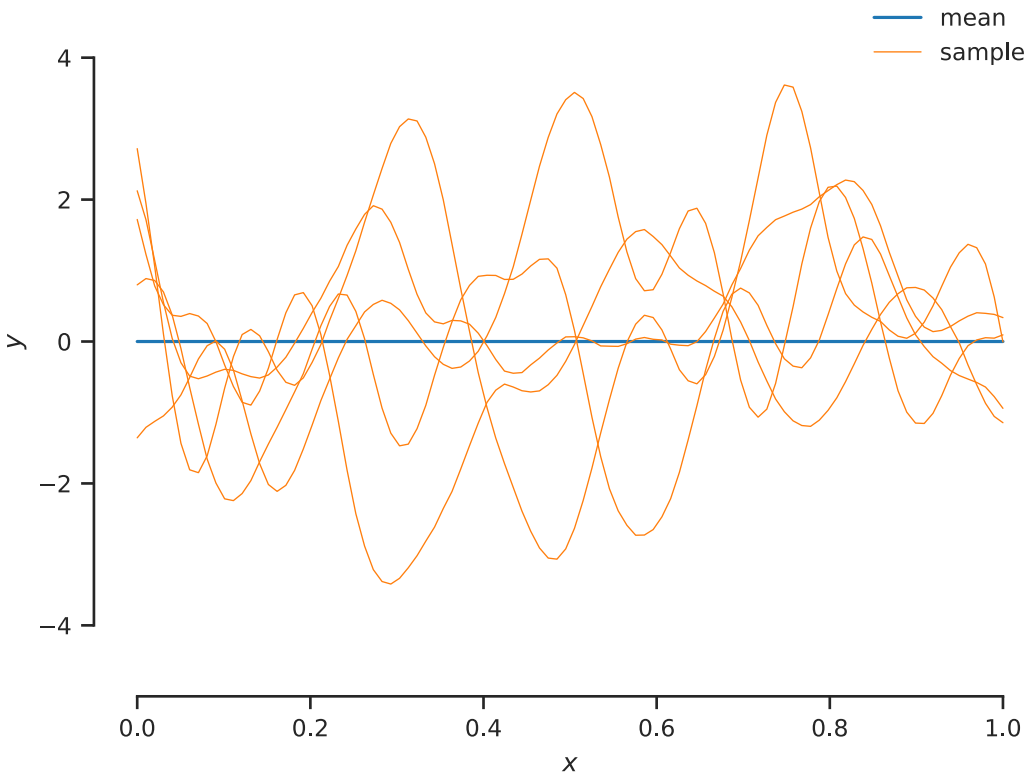
Assume that you hold the following beliefs + You know that $f(x)$ has as many derivatives as you want and they are all continuous + You don't know if $f(x)$ has a specific trend. + You think that $f(x)$ has "wiggles" that are approximatly of size $\Delta x = 0.05$. + You think that $f(x)$ is between -3 and 3.

**Answer:**

[ ]:
```
k = ScaleKernel(RBFKernel())
# Define the variance such that 2 * sigma = 3  ==>  sigma = sqrt(var) = 3 / 2
↪==> var = (3 / 2)^2
k.outputscale = (3 / 2) ** 2
k.base_kernel.lengthscale = 0.05

mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

sample_functions(mean, k, nugget=1e-4, num_samples=5)
```



### 1.4.3 Part C - Continuous function with known length scale

Assume that you hold the following beliefs + You know that $f(x)$ is continuous, nowhere differentiable. + You don't know if $f(x)$ has a specific trend. + You think that $f(x)$ has "wiggles" that are approximately of size $\Delta x = 0.1$. + You think that $f(x)$ is between -5 and 5.

Hint: Use `gpytorch.kernels.MaternKernel` with $\nu = 1/2$.

**Answer:**

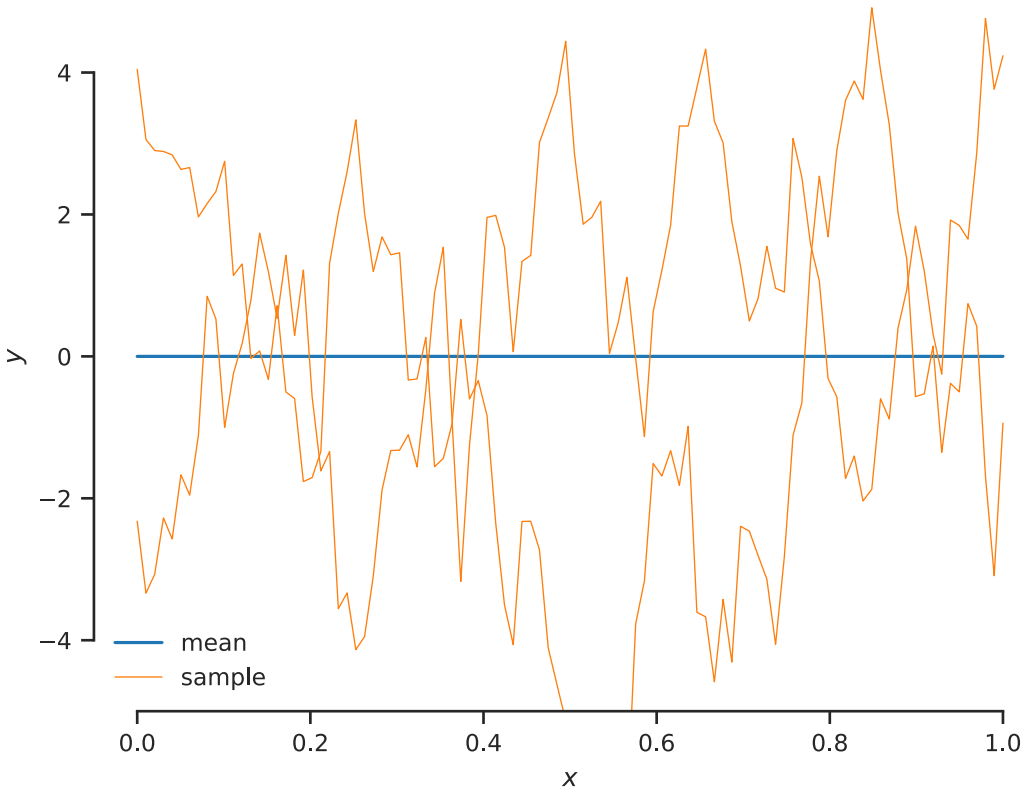
***Turning down the number of samples on these next few so that we can more clearly see what is going on***

[ ]:
```
from gpytorch.kernels import MaternKernel

k = ScaleKernel(MaternKernel(nu=1/2))
# Define the variance such that 2 * sigma = 5
k.outputscale = (5 / 2) ** 2
k.base_kernel.lengthscale = 0.1

mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

sample_functions(mean, k, nugget=1e-4, num_samples=2)
```



### 1.4.4 Part D - Smooth periodic function with known length scale

Assume that you hold the following beliefs + You know that $f(x)$ is smooth. + You know that $f(x)$ is periodic with period 0.1. + You don't know if $f(x)$ has a specific trend. + You think that $f(x)$ has "wiggles" that are approximately of size $\Delta x = 0.5$ of the period. + You think that $f(x)$ is between -5 and 5.

Hint: Use `gpytorch.kernels.PeriodicKernel`.

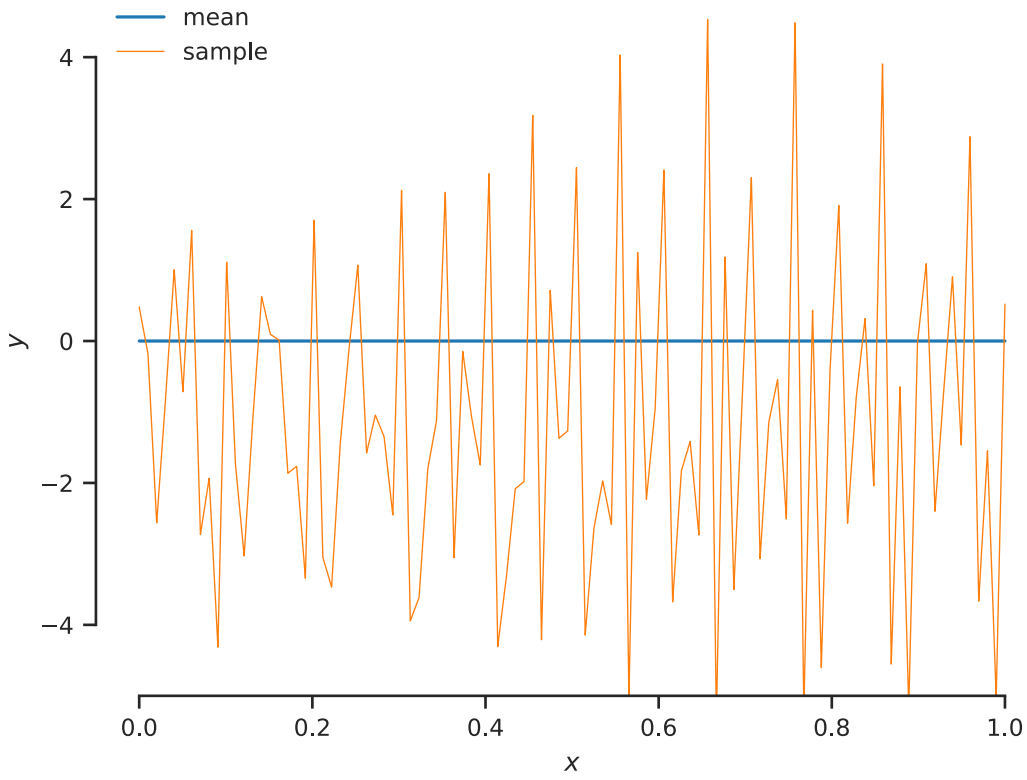
**Answer:**

[ ]:
```
from gpytorch.kernels import PeriodicKernel

k = ScaleKernel(PeriodicKernel())
# Define the variance such that 2 * sigma = 5
k.outputscale = (5 / 2) ** 2
period_length = 0.1
k.base_kernel.lengthscale = 0.5 * period_length
k.base_kernel.period_length = period_length

mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

sample_functions(mean, k, nugget=1.5e-4, num_samples=1)
# sample_functions(mean, k, nugget=1.5e-2, num_samples=1, )
```



### 1.4.5 Part E - Smooth periodic function with known length scale

Assume that you hold the following beliefs + You know that $f(x)$ is smooth. + You know that $f(x)$ is periodic with period 0.1. + You don't know if $f(x)$ has a specific trend. + You think that $f(x)$ has "wiggles" that are approximately of size $\Delta x = 0.1$ of the period (**the only thing that is different compared to D**). + You think that $f(x)$ is between -5 and 5.

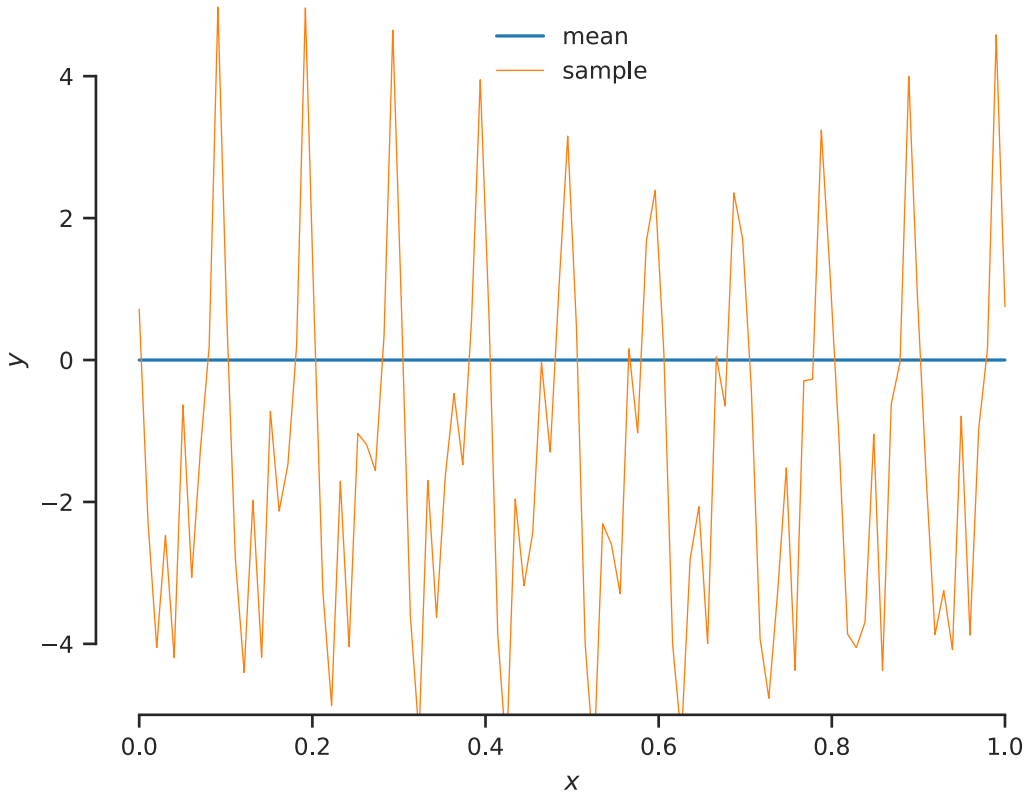
Hint: Use `gpytorch.kernels.PeriodicKernel`.

**Answer:**

[ ]:
```
k = ScaleKernel(PeriodicKernel())
# Define the variance such that 2 * sigma = 5
k.outputscale = (5 / 2) ** 2
period_length = 0.1
k.base_kernel.lengthscale = 0.1
k.base_kernel.period_length = period_length

mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

sample_functions(mean, k, nugget=4e-4, num_samples=1, num_test=100)
```



### 1.4.6 Part F - The sum of two functions

Assume that you hold the following beliefs + You know that $f(x) = f_1(x) + f_2(x)$, where: - $f_1(x)$ is smooth with variance 2 and length scale 0.5 - $f_2(x)$ is continuous, nowhere differentiable with variance 0.1 and length scale 0.1

Hint: Use must create a new covariance function that is the sum of two other covariances.

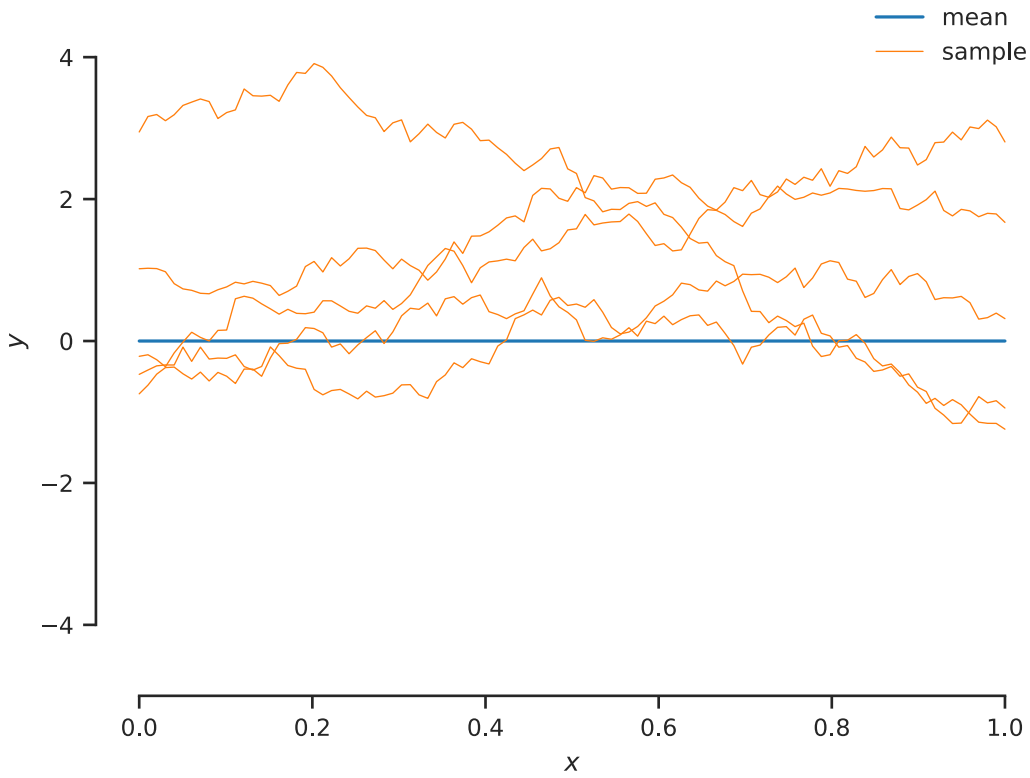
[ ]:
```
k1 = ScaleKernel(RBFKernel())
k1.outputscale = 2
k1.base_kernel.lengthscale = 0.5

k2 = ScaleKernel(MaternKernel(nu=0.5))
k2.outputscale = 0.1
k2.base_kernel.lengthscale = 0.1

k = k1 + k2

mean = gpytorch.means.ConstantMean()
mean.constant = 0.0

sample_functions(mean, k, nugget=1e-4, num_samples=5)
```



### 1.4.7 Part G - The product of two functions

Assume that you hold the following beliefs + You know that $f(x) = f_1(x)f_2(x)$, where: - $f_1(x)$ is smooth, periodic (period = 0.1), length scale 0.1 (relative to the period), and variance 2. - $f_2(x)$ is smooth with length scale 0.5 and variance 1.

Hint: Use must create a new covariance function that is the product of two other covariances.

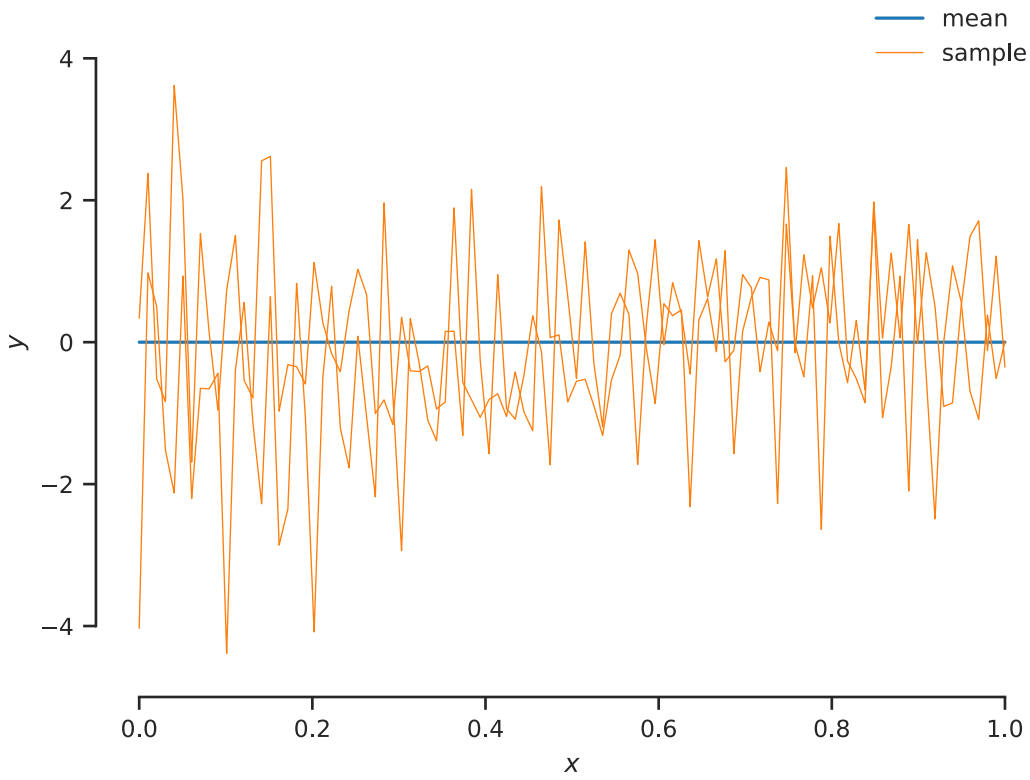
[ ]:
```
k1 = ScaleKernel(PeriodicKernel())
period_length = 0.1
k1.outputscale = 2
k1.base_kernel.lengthscale = 0.1 * period_length
k1.base_kernel.period_length = period_length

k2 = ScaleKernel(RBFKernel())
k2.outputscale = 1
k2.base_kernel.lengthscale = 0.5

k = k1 * k2

mean = gpytorch.means.ConstantMean()
mean.constant = 0.0
```

```
sample_functions(mean, k, nugget=1e-4, num_samples=2)
```



### 1.5 Problem 2

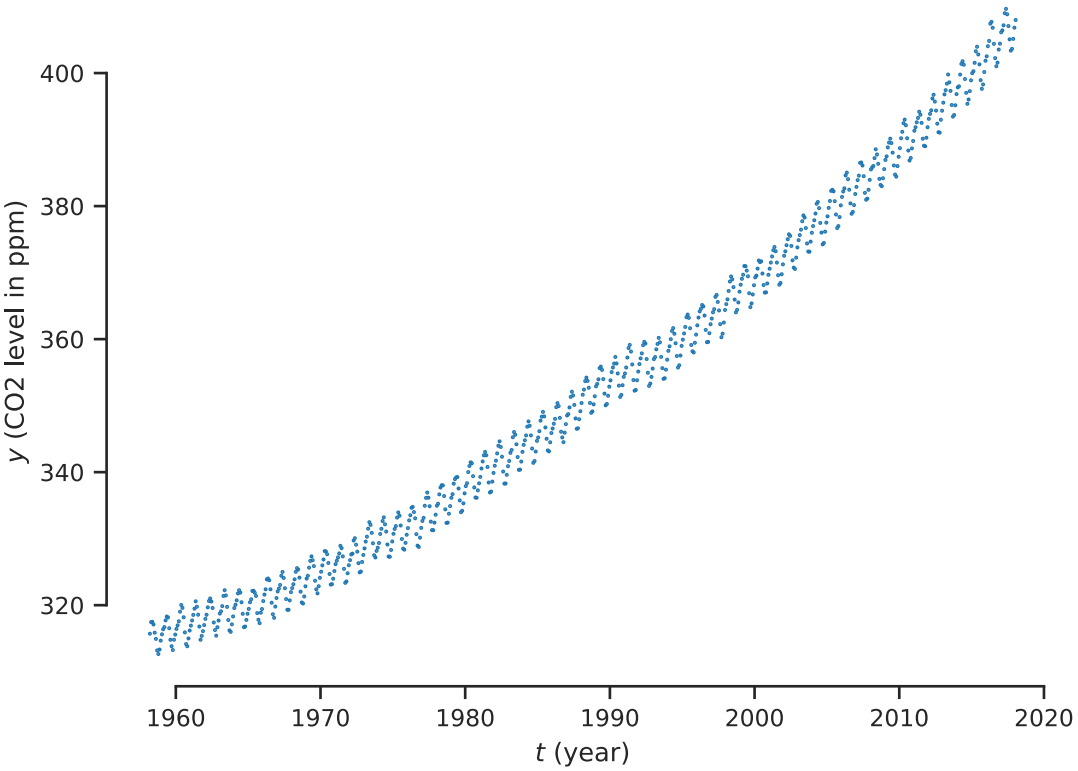
The National Oceanic and Atmospheric Administration (NOAA) has been measuring the levels of atmospheric CO2 at the Mauna Loa, Hawaii. The measurements start in March 1958 and go back to January 2016. The data can be found here. The Python cell below downloads and plots the data set.

[ ]:
```
# url = "https://github.com/PredictiveScienceLab/data-analytics-se/raw/master/
  ↪lecturebook/data/mauna_loa_co2.txt"
# download(url)
```

[ ]:
```
data = np.loadtxt('mauna_loa_co2.txt')
```

[ ]:
```
#load data
t = data[:, 2]  #time (in decimal dates)
y = data[:, 4]  #CO2 level (mole fraction in dry air, micromol/mol, abbreviated␣
  ↪as ppm)
fig, ax = plt.subplots(1, 1)
```

```
ax.plot(t, y, '.', markersize=1)
ax.set_xlabel('$t$ (year)')
ax.set_ylabel('$y$ (CO2 level in ppm)')
sns.despine(trim=True);
```



Overall, we observe a steady growth of CO2 levels. The wiggles correspond to seasonal changes. Since most of the population inhabits the northern hemisphere, fuel consumption increases during the northern winters, and CO2 emissions follow. Our goal is to study this dataset with Gaussian process regression. Specifically, we would like to predict the evolution of the CO2 levels from Feb 2018 to Feb 2028 and quantify our uncertainty about this prediction.

Working with a scaled version of the inputs and outputs is always a good idea. We are going to scale the times as follows:

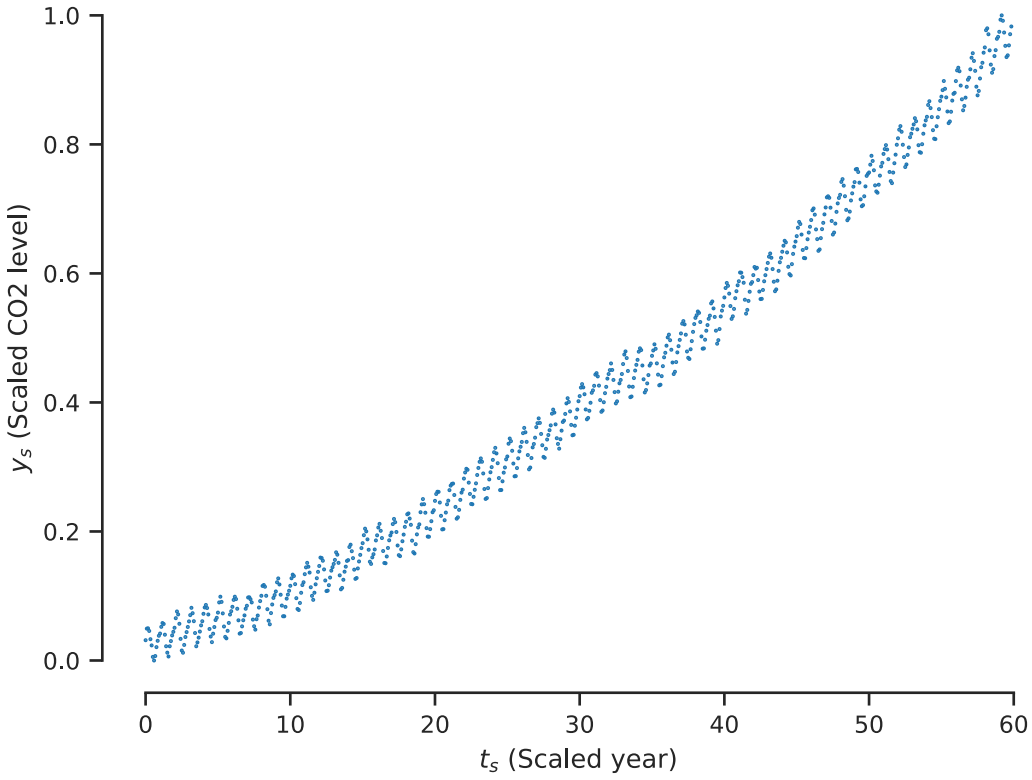
$$t_s = t - t_{\min}.$$

So, time is still in fractional years, but we start counting at zero instead of 1950. We scale the $y$'s as:

$$y_s = \frac{y - y_{\min}}{y_{\max} - y_{\min}}.$$

This takes all the $y$ between 0 and 1. Here is what the scaled data look like:

[ ]:
```
t_s = t - t.min()
y_s = (y - y.min()) / (y.max() - y.min())
fig, ax = plt.subplots(1, 1)
ax.plot(t_s, y_s, '.', markersize=1)
ax.set_xlabel('$t_s$ (Scaled year)')
ax.set_ylabel('$y_s$ (Scaled CO2 level)')
sns.despine(trim=True);
```



Work with the scaled data in what follows as you develop your model. Scale back to the original units for your final predictions.

### 1.6 Part A - Naive approach

Use a zero mean Gaussian process with a squared exponential covariance function to fit the data and make the required prediction (ten years after the last observation).

**Answer:**

**Again, this is done for you so that you have a concrete example of what is requested.**

[ ]:
```
cov_module = ScaleKernel(RBFKernel())
mean_module = gpytorch.means.ConstantMean()
train_x = torch.from_numpy(t_s).float()
train_y = torch.from_numpy(y_s).float()
naive_model = ExactGP(
    train_x,
    train_y,
    mean_module=mean_module,
    covar_module=cov_module
)
train(naive_model, train_x, train_y)
```

Notice that the squared exponential covariance captures the long terms but fails to capture the seasonal fluctuations. The seasonal fluctuations are treated as noise. This is wrong. You will have to fix this in the next part.

### 1.7 Part B - Improving the prior covariance

Now, use the ideas of Problem 1 to develop a covariance function that exhibits the following characteristics visible in the data (call $f(x)$ the scaled CO2 level. $+ f(x)$ is smooth. $+ f(x)$ has a clear trend with a multi-year length scale. $+ f(x)$ has seasonal fluctuations with a period of one year. $+ f(x)$ exhibits small fluctuations within its period.

There is more than one correct answer.

**Answer:**

Predict everything:

[ ]:
```
from gpytorch.kernels import ScaleKernel, RBFKernel, PeriodicKernel, RQKernel

# Model the long-term trend of the data
k1 = gpytorch.kernels.ScaleKernel(gpytorch.kernels.RBFKernel())
k1.outputscale = 1
k1.base_kernel.lengthscale = 40
```

```
# Model the short-term seasonal/periodic behavior of the data with a period of␣
 ↪1 year
k21 = PeriodicKernel(period_length_prior=gpytorch.priors.NormalPrior(1, 0.5))
k21.lengthscale = 0.6

# k22 = RBFKernel()
# k22.lengthscale = 0.3

k2 = ScaleKernel(k21)# * k22)
k2.outputscale = 2

# Model other small fluctuations not captured by the other two kernels
k3 = ScaleKernel(RQKernel())
k3.outputscale = 0.4
k3.base_kernel.alpha = 0.15
k3.base_kernel.lengthscale = 1

cov_module = k1 + k2 * k3

# Capture some of the overall trend of the data in the mean by making it linear
mean_module = gpytorch.means.LinearMean(1)

likelihood = gpytorch.likelihoods.GaussianLikelihood()

likelihood.noise = 0.05

model = ExactGP(
    train_x,
    train_y,
    mean_module=mean_module,
    covar_module=cov_module,
    likelihood=likelihood
)

param_names = []
pre_params = []
post_params = []

for name, v in model.named_parameters():
    param_names.append(name)
    pre_params.append(v.item())

Plot using the following block:

## 1.8 Part C - Predicting the future

How does your model predict the future? Why is it better than the naive model?

**Answer:** The model predicts the future better than the naive model. It performs better than the naive model because of the covariance kernels and mean function used to model the data. The naive model does not account for the seasonal fluctuations in the data, but we know that these fluctuations occur periodically every year. We can model this into our covariance kernel, and we can also account for the other long-term and short-term trends as described in the comments above. The periodic nature of the data is clearly shown in the extrapolation into the future, and the overall trend is also followed well.

## 1.9 Part D - Bayesian information criterion

As we have seen in earlier lectures, the Bayesian informationc criterion (BIC), see this, can bse used to compare two models. The criterion says that one should: + fit the models with maximum likelihood, + and compute the quantity:

$$\text{BIC} = d\ln(n) - 2\ln(\hat{L}),$$

where $d$ is the number of model parameters, and $\hat{L}$ the maximum likelihood. + pick the model with the smallest BIC.

Use BIC to show that the model you constructed in Part C is indeed better than the naïve model of Part A.

```

Although the BIC is higher for the model, this is likely due to the added complexity of the model. We can drive our BIC down to an very low level and still fit the data okay, but our model does a better job at actually modeling the patterns of the data. The fact that the BIC is not orders of magnitude higher than the naive model verifies that it is a reasonable model, and we visually check the characteristics that it provides in order to judge that it follows the data better in this regard.
